Here we go apes, it's time for some wild speculation.

So here are some facts

1. Ryan Cohen bought 100k shares today and they're with his other shares in computershare.
2. Apes have been averaging 43k shares DRS per trading day
3. We traded 14M shares today.

Here's something that seems right to me, based on watching GME, but I don't have data for.

4. Our average volume for the last number of months has been about 4M per day.

Tinfoil

So Cohen bought 100k shares today, which realized a 10M share increase in traded volume. If what we're seeing is the shorts that are closed as a result of shares being pulled from the market, then shorts are leveraged at 100 shorts for every share of GME. The conclusion from this would be that all of the lit market action we're seeing on GME is due to shares being DRS and the shorts that close because of them.

$43k \times 100 = 4.3M$  which I think is around our daily average volume. This would assume that most other orders are internalized and never see markets, but I wouldn't doubt that at this point.

TLDR: Every share put into computershare pulls 100 shorts from the market. Maybe. I did name this wild speculation for a reason.
