I was musing yesterday that a lot of stocks in the so called "meme basket" category suddenly started getting a lot volume mid-afternoon. For instance BB here:

[Avg. Volume 9,210,904 - Today's Volume: 34,468,388](<https://preview.redd.it/ce8xkbqvjmu71.png?width=640&format=png&auto=webp&s=ce2dcc947da417f0d4070d9532b9ba5bf12943f6>)

Note: the above chart represents a 3.8x increase in volume above the average. And if you look back at the 6 month charts, you can actually see spikes happening in roughly monthly cycles too. I would like to then pose the question to the venerable wrinkle brains here if it could be possible that what we are seeing are the results of T+21/T+35 cycles still occurring? So, instead of letting the GME price go up openly, they are now using variance swaps to suppress the price during their buy-ins, and that is why these cycles have seemingly disappeared from view. Normally it seems like most days they prefer using AMC as their main ticker for variance swaps, but if I recall AMC also follows a similar T+21/T+35 cycle. If that is the case then during these critical periods there suddenly becomes a need to suppress both AMC and GME simultaneously, which is perhaps why we see this result of a brief flurry of activity in other assorted tickers?

Lastly I think there is also one other key element in all of this, and that is the state of the collateral markets. It sure looks like if there is a lot of strain in the collateral market, and then GME lands on a cycle date the price of GME goes up. Otherwise if the collateral markets are tranquil, you can expect sideways trading and afterwards it's back to businesses as usual.
