these volumes are at half hour intervals, and let's assume it excludes pre/post market trading, so 7 hours * 2 = 14 intervals per day

so the two biggest spikes are a bit less than the halfway point of 1.25m, let's say they are 1m average shares per half hour, and they seem to cover about 1/3rd of the day so:

$2 \cdot (1 \cdot (14/3)) =$ about 9m shares covered

the other red squares highlight the other significant spikes that happened, let's say they average out to 400k shares/half hour, and they cover about 4.5 days, so $4.5 \cdot 14 = 63$ half intervals
 the last bit, let's say are about 200k shares/half hour, and they cover 5 days = 70 half intervals and so

$.4 \cdot 63 =$ about 25m shares covered

$.2 \cdot 70 =$ about 14m shares covered

TOTAL shares covered in January based on SEC data

= 48m shares
vs
GME float of 63m shares

If we include pre market and after hours, it could certainly be a lot more than what I estimated
