If 35 million GME shares are DRS'ed then the available float drops from 46m to 11m shares.

GameStop is officially sold short around 11m shares so this is 100% sold short on available float.

As official short interest goes up in count, the proportion needing DRS goes down at an exponential rate. Lets walk through one example. Assume short interest goes to 22 million or double where it is now; the available float would need to be reduced to 22m from 46m via DRSing only 24m shares.

If SI triples to 33m then only 13m need be DRS to make the available float be 100% short. If they really don't over sell short then the SHF have nothing to worry about and we will be proven wrong.

We know that short interest is an official number and an unofficial number that's much higher due to black box effect (long term PFOF accounting).

Thoughts?
