EDIT: The below, I feel is probably inaccurate. I tried to do something but I think things are wrong (like assuming 15 minutes of trade halt time, and just not explaining my thesis properly). I'm going to leave the original up and wouldn't mind people reaching out to improve the hypothesis, because I am actually interested in coming up with a good estimate of how long it would take to hit 40/50/60 million. thanks!

Good Day, Fellow HODLers! Was talking with u/disoriented_llama about the MOASS last night and I had forgotten about the trading halts that would occur during an exponential curve rocket moon occurrence. As such, I want to give r/TheGloryHodl the worldwide exclusive!

I honestly haven't seen anyone post this type of DD, but of course I'm just one person so it doesn't mean anyone has done it... but be kind as this is really my first post about data for other apes.

SCENARIO:

1. Based on a starting price of \$350, which seems to be a consensus number for the rocket to ignite
2. No AH price changes, which is highly unlikely when the stonk goes parabollic
3. Based on a trading halt immediately after market open... maybe not likely on the first day, but one could assume that there is no stopping the stock after a full day of 26 halts
4. 2 pm on the fifth day is when it breaks \$40 mil (~43 Mil at that time)

Hope you enjoy.
