I haven't seen this discussed yet and is probably wrong, but I'd like a wrinkly ape to explain. Float seems a semi vague topic that could be open to interpretation. My understanding is that tied up shares by insiders and institutions that don't trade freely are outside of the float.

Is there a chance that our directly registered shares at computershare for gme are technically considered outside the float since we know they are not very liquid? Rephrased, is the float simply those shares that are held in street name with the dtcc (cede and co.)?

If whenever the float gets recalculated (daily, monthly, annually?) we see a decrease, and institutions and insiders have not sold, I think that answers my question.

I don't think it's the case, just wondering if anyone has any firm proof.

Also when RC bought 13% of shares late last year, I believe that is what caused the sneeze. What if apes similarly collectively pull 13% of all real shares over to DRS?
