I truly believe that the inevitable FOMO will come in stages so I'm curious in getting some wrinkled opinions.

First, it's no secret that the lower GME goes in price per share, the bigger the surge in buys from apes.

Lower price = more shares.

But I'm wondering if there will be a similar effect on apes when we see more of the float locked up from DRS'ing.

For example, if 80% of the float is locked up, then I know that I'm going to get uncomfortably more aggressive with buying more shares. That way I can gobble up the last remaining shares with MOASS just around the immediate corner (assuming it hasn't started).

More DRS = quicker returns

So, like with a lower share price, are we expecting an initial wave of FOMO from apes as we get closer to DRS'ing the float?

And if so, any input on the % of float that will cause panic buys?

Similarly, I'm skeptical that news outlets will let the masses know when % of DRS. Or that the masses will understand the DRS situation from a headline.

So it seems like ape FOMO would kick things off before the inevitable FOMOASS of paper hands once they hear about price increase.

If that's the case, then I'm curious what price point will weed out most people. We know people will buy shares at around \$400, however, will the average Joe keep buying at \$1k? \$10k? \$100k/share?

And then the next part of FOMOASS would be from hedgies?

Sorry that this post is filled with questions and not DD!

I'm primarily asking because I can't help but assume that the DRS rate will become exponential once FOMO starts.

What are your thoughts?
